CL13: Big-O Notation

Announcements

- Exercise 4 - List Utils
 - “extend” should not be using in built-in extend method!
 - I’ll extend the deadline through *tomorrow* for you to make changes
 - After you re-submit exercise, submit a regrade request!
- Quiz 03
 - Multiple Choice: Big-O Runtime, Unit Tests, Dictionaries
 - Memory Diagram: Dictionaries, Functions
 - Short Response: Unit Tests and Dictionary Syntax
 - Function Writing: Dictionaries
 - ***Monday’s class will be a virtual review session!!!***

Recall: Algorithms

Input is data given to an algorithm

An **algorithm** is a series of steps

An algorithm **returns** some **result**

An algorithm *may* be influenced by its **environment** and it *may* produce side-effects which influence its environment.

What is an algorithm?

- A set of steps to solve a general problem
- Finite
- Can handle a problem of arbitrary size

How do we measure how “good” an algorithm is?

- Is it correct?
- How long does it take to implement?
- How much computer memory does it take?

Why do we care about computation speed?

- Security: Cryptography works because encrypted information takes *too long* to decipher!
- User Experience: Users don't want to work with a slow application!
- Big Data: We want to be able to feed as much data as possible into our systems, but we need a way to *efficiently* do that!

Measurements We Use

- O “Big O”: upper bound (worst case runtime)
- Ω “Big Omega”: lower bound (best case runtime)
- Θ “Big Theta”: average runtime

Returning to Finding the Lowest Card in a Deck

- Go from left to right
- Remember the lowest card you've seen *so far* and compare it to the next cards

Finding the Lowest Card

Low card:

Finding the Lowest Card

Low card:

Finding the Lowest Card

Low card:

Finding the Lowest Card

Low card:

Finding the Lowest Card

Low card:

Finding the Lowest Card

Low card:

4 actions for input of 4 cards.

Finding the Lowest Card

Low card:

4 actions for
input of 4 cards.

n actions for
input of size n.

Finding the Lowest card

- In this approach, we always have to check every card in the deck, so our runtime will always be approximately n where n is the size of the deck.

Finding the minimum $\in O(n)$

Finding the minimum $\in \Omega(n)$

Finding the minimum $\in \Theta(n)$

Speed vs. Memory

- Sometimes you can make a tradeoff between speed and memory.
- E.g. storing a value rather than computing it repeatedly.

```
1 def find_min1(nums: list[int]) -> int:
2     min_idx: int = 0
3     idx: int = 0
4     while idx < len(nums):
5         if nums[idx] < nums[min_idx]:
6             min_idx = idx
7             idx += 1
8     return min_idx
9
10 def find_min2(nums: list[int]) -> int:
11     min_idx: int = 0
12     min_val: int = nums[min_idx]
13     idx: int = 0
14     while idx < len(nums):
15         val: int = nums[idx]
16         if val < min_val:
17             min_idx = idx
18             min_val = val
19         idx += 1
20     return min_idx
21
22 search_vals: list[int] = [10, 9, 8]
23 find_min1(search_vals)
24 find_min2(search_vals)
```

New Example: Finding a specific card.

- Go from left to right
- The first time you see your card, exit!

Finding 3

Finding 3

Finding 3

Worst Case

What is the worst case input for this algorithm? (What will make us look at the *most* cards before exiting?)

What is the Big-O (worst case) runtime in terms of deck size n ?
